SUMMARY

In July and August 1990, the National Institute for Occupational Safety and Health (NIOSH) received requests from the Actors' Equity Association (AEA) and the League of American Theatres and Producers, Inc. (LATP) to investigate possible health effects associated with the use of theatrical "smoke" in Broadway productions. In 1991, NIOSH representatives conducted site visits, summarized in the revised interim report provided as an appendix to this report. In 1993, NIOSH investigators conducted a follow-up investigation to further characterize "smoke" exposures and to determine whether there were measurable respiratory effects among performers.

INITIAL SURVEY: JUNE 17 AND JULY 2, 1991

Four Broadway productions (Les Miserables, Miss Saigon, Phantom of the Opera, and Grand Hotel) using theatrical "smoke" were selected for study. Dress rehearsals were arranged to conduct personal breathing-zone (PBZ) and general area (GA) air sampling to quantitate the "smoke" exposure. A questionnaire was administered to the actors; it addressed the frequency and severity of irritant and respiratory symptoms associated with exposure to theatrical "smoke." A small number of PBZ air samples were collected on electricians, carpenters, and other personnel who may have been exposed to the theatrical "smoke" during a performance. To determine if the prevalence of symptoms among actors in shows using theatrical "smoke(s)" differed from the symptom prevalence in non-"smoke"-using productions, NIOSH investigators administered the same questionnaire to performers in five Broadway productions in which no theatrical "smoke" was used (Lost in Yonkers, Gypsy, Getting Married, Once on This Island, and Six Degrees of Separation).

Although theatrical "smoke" was visibly evident during all of the "smoke" performances, concentrations of potential airborne contaminants from all of the PBZ and GA air samples were very low when compared to applicable Occupational Safety and Health Administration (OSHA) Permissible Exposure Limits (PELs), American Conference of Governmental Industrial Hygienists (ACGIH) Threshold Limit Values (TLVs), or NIOSH Recommended Exposure Limits (RELs). For example, acrolein and acetaldehyde, suspected to be possible decomposition products from the heating of the glycol-based fog fluids, were not found in any of the PBZ or GA air samples. None of the PBZ air samples had detectable amounts of formaldehyde.

Although 120 PBZ and GA air samples were collected for glycols (specifically ethylene, propylene, 1,3-butylene, diethylene, and triethylene glycols) during this investigation,
NIOSH chemists subsequently determined that NIOSH Sampling and Analytical Method No. 5500 developed for ethylene glycol was inadequate to identify and quantitate other glycols. In at least one instance, ethylene glycol was incorrectly identified in an air sample. Since it was possible that interferences from other glycol analytes could have occurred, quantitative results could not be reported. Qualitatively, glycols were present in some of the PBZ and GA samples collected in all four theatrical productions in which sampling was conducted.

Air samples (both PBZ and GA) were collected for mineral oil mist during a dress rehearsal of *Miss Saigon*. Concentrations ranged up to 1.35 milligrams per cubic meter (mg/m³), time-weighted average (TWA) over the duration of the play. The highest levels were measured in GA samples positioned on stage. All of the measured concentrations were well below the OSHA, NIOSH, and ACGIH exposure criteria of 5 mg/m³ for up to a full-shift (8 to 10 hours) TWA exposure.

All 224 actors from nine Broadway productions completed questionnaires. Of this group, 134 questionnaires (60%) were from actors appearing in the four productions using theatrical "smoke," and 90 questionnaires (40%) were from actors appearing in the five control productions. When compared to actors from the non-"smoke" productions, actors from two or more of the four productions utilizing theatrical "smoke" reported experiencing a significantly greater prevalence of nasal symptoms (sneezing, runny or stuffy nose), respiratory symptoms (cough, wheeze, breathlessness, chest tightness), and mucous membrane symptoms (sore throat, hoarseness, dry throat, itchy/burning eyes, dry eyes) during their performances for the week prior to the survey.

**FOLLOW-UP SURVEY: NOVEMBER 18 - DECEMBER 4, 1993**

The medical portion of this follow-up was conducted in two phases and designed to evaluate the relationship between acute changes in the lung function and "smoke" exposure status among performers reporting symptoms consistent with occupational asthma. In the first phase of the evaluation, NIOSH investigators administered a screening questionnaire to all performers in three "smoke" productions (*Les Miserables, Miss Saigon, and Phantom of the Opera*) and three non-"smoke" productions (*Any Given Day, She Loves Me, and The Sisters Rosenzweig*). The purpose of the screening questionnaire was to identify performers with symptoms suggestive of occupational asthma. All symptomatic performers, and a random sample of non-symptomatic performers, were invited to participate in the follow-up case-control study (Phase II).

The environmental evaluation consisted of GA air samples collected during live performances of *Les Miserables, Miss Saigon, and Phantom of the Opera*. Since special dress rehearsals could not be arranged, no PBZ air sampling was conducted. Air samples were collected for glycols, aldehydes (formaldehyde and acrolein), mineral oil mist (*Miss Saigon*), and volatile organic compounds.
Thirty-seven symptomatic and 68 non-symptomatic performers made up the Phase II study population of 105 performers. All participants were asked to complete a self-administered questionnaire addressing medical and work history. Participants were also asked to perform, after verbal instruction, serial determinations of their peak expiratory flow rate (PEFR) using portable flow meters. Of the 105 participants, 65 (62%) submitted at least a partial questionnaire or PEFR information. Five persons met the case definition for theatrical work-related occupational asthma. Three of these five were exposed to theatrical "smoke" during the study and two were not. Of the 60 persons who did not meet the case definition, 16 had been identified as being "symptomatic" in the Phase I portion of the evaluation, and were therefore excluded from further analysis. This left 45 non-case performers; 27 of these were "smoke"-exposed and 18 were not. The odds ratio (OR) for the association between being a case and being "smoke"-exposed was 1.0 (95% confidence interval [CI] = 0.1-13.1). This indicates that performers with asthma-like symptoms and abnormal peak-flow meter results ("cases") were not more likely to have been exposed to theatrical "smoke" when compared to persons who did not meet this case definition.

Analysis of the bulk samples revealed the expected glycols, based on information provided by the manufacturers. Two of the three samples contained propylene glycol, 1,3-butylene glycol, and triethylene glycol as the major components. The remaining bulk sample contained ethylene glycol and diethylene glycol as the major components, with trace amounts of triethylene glycol and propylene glycol.

Ethylene glycol was sampled in two of the three productions (Phantom of the Opera and Miss Saigon) at concentrations of 0.4 mg/m³ or less, well below the OSHA PEL of 127 mg/m³. Propylene glycol was detected in samples from all three productions, ranging from <0.01 to 1.9 mg/m³. Triethylene glycol and 1,3-butylene glycol were detected only in Les Miserables, ranging from <0.04 to 3.7 mg/m³ and 0.16 to 2.1 mg/m³, respectively. Formaldehyde concentrations, using NIOSH Sampling and Analytical Method 3500 (sodium bisulfite-filled impingers), ranged from <0.002 to 0.04 parts per million (ppm), well below the OSHA and ACGIH exposure criteria. These formaldehyde concentrations are typical of those which NIOSH investigators have measured in non-industrial work places. Acrolein was not detected on any of the GA samples (Minimum Detectable Concentration [MDC] = 0.016 mg/m³). Oil mist concentrations were below 0.13 mg/m³, far below NIOSH, OSHA, and ACGIH exposure criteria of 5.0 mg/m³ (TWA). The thermal desorption analysis revealed that only two samples (from Phantom of the Opera) contained even modest concentrations; levels of compounds detected on all other samples were very low. Major compounds detected were mostly C₉-C₁₂ aliphatic hydrocarbons and C₉H₁₂ alkyl benzenes (trimethyl benzenes, propyl benzenes, etc.). Other compounds identified on these included 1,1,1-trichloroethane, acetaldehyde, acetone, isopropanol, toluene, limonene, siloxanes, and perchloroethylene.
Based on the results of this study, there is no evidence that theatrical "smoke," at the levels found in the theaters studied, is a cause of occupational asthma among performers. Some of the constituents of theatrical "smoke," such as the aerolized glycols and mineral oil, could have irritative or mucous membrane drying properties in some individuals. Therefore, it is reasonable to minimize exposures by such means as relocating "smoke" machines to avoid exposing actors to the direct, concentrated release of the aerosols, minimizing the amount of "smoke" necessary for the production, and using only fog fluids approved by the manufacturers of the machines. The glycols used should be at the level of "food grade" or "high grade." Glycol-based systems should also be designed to heat the fog fluids only to the lowest temperature needed that achieve proper aerosolization. This would help to avoid overheating the fluid and minimize the generation of decomposition products.

INTRODUCTION

In July and August 1990, the National Institute for Occupational Safety and Health (NIOSH) received requests for a Health Hazard Evaluation (HHE) from the Actors' Equity Association (AEA) and the League of American Theatres and Producers, Inc. (LATP) to investigate possible health effects associated with the use of theatrical "smoke" in Broadway productions. NIOSH representatives conducted site visits in January and June 1991, which were summarized in the NIOSH revised interim report dated October 1, 1992 (Appendix A). The interim report noted a high prevalence of work-related lower respiratory symptoms (cough, wheeze, chest tightness, and shortness of breath) consistent with occupational asthma among the "smoke"-exposed performers. NIOSH investigators conducted a follow-up investigation to further characterize exposures to the "smoke" and to determine whether there were measurable respiratory effects among performers.

BACKGROUND

THEATRICAL "SMOKE"

Many of the theatrical "smokes" currently used by Broadway theaters, television, and motion pictures utilize heated glycol fluids to produce a visible aerosol. Workers engaged in these various shows are therefore exposed to theatrical "smoke" by inhalation. Although the exact formulations of these fluids are considered proprietary by the manufacturers, some of the more commonly used glycols include ethylene glycol, propylene glycol, 1,3-butylene glycol, diethylene glycol, and triethylene glycol. All of the "smoke" productions included in this survey used a glycol-based "smoke" generation system. Sizes of the glycol-based "smoke" systems ranged from larger units (permanently mounted either on or off stage) to smaller, hand-held devices operated by stage hands during a performance. In addition to the glycol-based "smoke" systems, some of the productions used dry ice (carbon dioxide) fog systems. In one of the Broadway productions (Miss Saigon) an unheated mineral oil-based "smoke" generation system was also used. The compounds in theatrical "smoke" are not known to cause or contribute to pulmonary function abnormalities, although only a few studies have addressed this potential problem.

1991 EVALUATION

In the summer of 1991, four Broadway productions (Les Miserables, Miss Saigon, Phantom of the Opera, and Grand Hotel) which used theatrical "smoke" were selected for study. Dress rehearsals were arranged to conduct personal breathing-zone (PBZ) and general area (GA) air sampling and to administer a questionnaire to the actors detailing the frequency and severity of irritant and respiratory symptoms following exposure to theatrical "smoke." In addition, a small number of PBZ air samples were collected on electricians, carpenters, and other personnel who may have been exposed to the theatrical "smoke" during a
To determine if the prevalence of symptoms among actors in shows using theatrical "smoke" differed from the symptom prevalence in non-"smoke" productions, NIOSH investigators also administered the same questionnaire to actors in five Broadway productions in which no theatrical "smoke" was used (Lost in Yonkers, Gypsy, Getting Married, Once on This Island, and Six Degrees of Separation). The actors in these non-"smoke" productions are termed "non-exposed" in this report.

In the 1991 study (Appendix A), all 224 actors from nine Broadway productions completed questionnaires (Appendix B). Of this group, 134 questionnaires (60%) were from actors appearing in the four productions using theatrical "smoke," and 90 questionnaires (40%) were from actors appearing in the five non-"smoke" productions.

When compared to actors from the non-"smoke" productions, actors from two or more of the four productions utilizing theatrical "smoke" reported experiencing a significantly greater prevalence of respiratory symptoms (cough, wheeze, breathlessness, chest tightness) and other symptoms during their performances for the week prior to the survey. Although theatrical "smoke" was visibly evident during all of the performances, concentrations of "smoke" constituents in all of the PBZ and GA air samples collected were very low when compared to current occupational exposure criteria (Occupational Safety and Health Administration [OSHA] Permissible Exposure Limits [PELs], American Conference of Governmental Industrial Hygienists [ACGIH] Threshold Limit Values [TLVs], or NIOSH Recommended Exposure Limits [RELs]). Thus, the reason for the high prevalence of symptoms, especially lower-respiratory symptoms, in the productions that used theatrical "smoke" was not clear since the ACGIH TLV and OSHA PEL for at least one of the glycols (ethylene glycol) are intended to minimize irritation of the respiratory passages. As discussed in Appendix A, heated glycol-based fog solutions have the potential to generate decomposition products such as acrolein and formaldehyde. These compounds have been associated with asthma and asthma-like symptoms. However, acrolein, acetaldehyde, and formaldehyde were not detected in any of the PBZ or GA samples in either the initial or follow-up surveys.

Because of the high prevalence of lower-respiratory symptoms in the "smoke"-exposed acting group, further study was undertaken by NIOSH in November 1993. Participants were informed of their test results in August 1994.

**EVALUATION DESIGN AND METHODS**
INDUSTRIAL HYGIENE

The industrial hygiene portion of the follow-up survey, performed on November 20, 1993, involved collecting GA air samples for glycols (ethylene, propylene, 1,3 butylene, diethylene, and triethylene glycols), mineral oil mist, aldehydes (formaldehyde, acrolein), and volatile organic compounds. Samples were collected at *Les Miserables, Miss Saigon,* and *Phantom of the Opera.* Since completing the 1991 NIOSH survey, one play (*Grand Hotel*) had closed. NIOSH investigators decided not to obtain a replacement for this production.

**Environmental Design**

In the initial environmental survey, PBZ and GA air samples were collected during specially arranged dress rehearsals. However, in this follow-up evaluation, air sampling was only conducted during "live" performances, an arrangement which necessitated collecting only GA samples to avoid disturbing the actors and the performance. The air sampling equipment was positioned so as not to interfere with the performance.

Where possible, air samples were collected on or near the stage. In addition, air samples were collected in the orchestra pit, break/lunch areas, off-stage dressing areas, property rooms, sound and lighting control booths, and the stage manager's office. Sampling times generally exceeded the length of the play since samples needed to be set up approximately 45 minutes to one hour before the play. In *Les Miserables,* several on-stage air samples were set up to compare the differences (if any) in the concentrations of glycols and aldehydes between the first and second acts.

Table 1 summarizes the sampling and analytical methods used in the 1993 follow-up study.

**Glycol Bulk Sample Analysis**

As during the 1991 survey, bulk samples of fluids used in the glycol-based theatrical fog-generating machines were collected from the devices in use at each of the theaters. These bulk samples were then submitted for laboratory analysis. The bulk samples were heated to specified temperatures and analyzed for volatile organic compounds by gas

---

*a* For air samples situated on-stage (or in other off-stage "quiet" areas), the battery operated air flow pump was placed in a sound-attenuating cardboard enclosure and typically hidden in a prop or behind scenery. The collection device, connected to the air flow pump by Tygon® tubing, was placed outside of the pump enclosure.

*b* The temperatures selected for the headspace analysis corresponded to the levels to which the glycol solutions were heated in their respective "smoke" machines.
chromatography-mass spectrophotometry (GC-MS). All of the bulk solutions were also analyzed directly for major glycol constituents.

**Development of a New Glycol Air Sampling Method**

The most significant change between the 1991 and 1993 environmental surveys was the development of a new NIOSH sampling and analytical method for airborne glycols. Intended as a replacement for the old NIOSH Method 5500 (the glycol method used in the 1991 survey), this new method is currently in internal NIOSH review and should appear as a supplement to the new 4th Edition of the NIOSH Manual of Analytical Methods.

In 1991, following collection of PBZ and GA air samples for glycols during the dress rehearsals, NIOSH chemists subsequently determined that NIOSH Method 5500 had deficiencies when used to identify and quantitate ethylene glycol and other similar glycols. For example, in at least one instance ethylene glycol was incorrectly identified in an air sample. Since it was possible that interferences from other similar glycol analytes could have occurred, the quantitative results initially reported were retracted. (see Appendix A) As a result, the only conclusion which should be drawn from the 1991 glycol air sampling data is that, qualitatively, airborne glycols were present in all four theatrical productions sampled in 1991.

The new NIOSH method uses a sorbent tube manufactured by SKC (No. 226-57). The tube contains 200 and 100 milligrams of XAD-7 in the front and back sections, respectively. It also has a built-in glass fiber pre-filter. Once collected, the samples are stable for at least 14 to 28 days and sample shipment is routine. Following desorption in 2 milliliters of methanol, the samples are analyzed by a gas chromatograph equipped with a flame ionization detector. The estimated analytical limit of detection is between 5 and 10 micrograms per sample.

**MEDICAL**

The medical portion of this HHE, which was conducted in two phases from November 20, 1993, through December 4, 1993, evaluated the relationship between acute changes in lung function and "smoke" exposure status in performers reporting symptoms consistent with occupational asthma. Prior to the data collection, a conference was held with representatives from the AEA and LATP and interested performers. At this conference, an overview of the study and instructions for participation were given and questions were answered.

**Phase I (November 1993) - Selection of Subjects**
NIOSH investigators invited all performers in three "smoke" productions (*Les Miserables*, *Miss Saigon*, and *Phantom of the Opera*) and three non-"smoke" productions (*Any Given Day*, *She Loves Me*, and *The Sisters Rosenzweig*) to participate in the medical study. Performers were recruited at the individual theaters. The first phase of the study included a screening questionnaire (Appendix C) which was administered to every available performer to identify individuals with symptoms suggestive of occupational asthma. Respondents reporting either:

1. wheezing (day or night)

   or

2. both shortness of breath (day or night) and chest tightness occurring "sometimes," "often," or "always" within the last 10 days were termed "symptomatic" and were invited to participate in Phase II. Performers not reporting these symptoms were selected as controls. All participants signed informed consent forms.

**Phase II (November - December 1993) - Case Control Study**

The following information was collected on both symptomatic and asymptomatic performers.

**Questionnaire**

A self-administered questionnaire (Appendix D) was provided that addressed medical and work history and the presence of pre-existing asthma or other respiratory illness. All participants signed a second informed consent form.

**Peak Expiratory Flow Rates**

To identify changes in the amount of air that can be exhaled over time (both in and out of the workplace), serial determinations of the peak expiratory flow rate (PEFR), using Wrights portable flow meters, were obtained. Peak flow refers to the amount of air in liters per minute that can be blown through the flow meter in one sharp breath. Peak expiratory flow rates were measured serially for two weeks. The measurements were to be taken upon awakening for the day, upon leaving for work, upon arrival to work, immediately prior to the show, immediately after the show, upon arrival home from the show, immediately before going to bed, during the night if awakened for any reason, and at other times respiratory symptoms were being experienced. The participants were instructed in the proper use of the portable flow meters by NIOSH investigators. Three exhalations were recorded each time, and the maximum of the three was accepted as the PEFR determination. Any wheezing, shortness of breath, chest tightness, cough, or other symptoms experienced at the time of a PEFR determination was reported on the peak flow record.

**Data Analysis**
Analyses were done using Epi Info, version 6.0. The following case definition was used for theatrical "smoke"-related occupational asthma in this evaluation.

1. Symptoms suggestive of asthma as defined above (Phase I).

   \[ \text{AND} \]

2. Symptomatic bronchial lability. The criteria for symptomatic bronchial lability was the participant's contemporaneous report of the following symptoms as his or her PEFR reached the minimum for the day or week:

   (a) wheezing (day or night)

   \[ \text{OR} \]

   (b) both shortness of breath \text{AND} either chest tightness or cough

**EVALUATION CRITERIA**

**GENERAL**

As a guide to the evaluation of the hazards posed by workplace exposures, NIOSH field staff employ environmental evaluation criteria for the assessment of a number of chemical and physical agents. These criteria are intended to suggest limits of exposure to which most workers may be exposed up to 10 hours per day, 40 hours per week for a working lifetime without experiencing adverse health effects. It is, however, important to note that not all workers will be protected from adverse health effects even though their exposures are maintained below these limits. A small percentage may experience adverse health effects because of individual susceptibility, a pre-existing medical condition, or a hypersensitivity (allergy). In addition, some hazardous substances may act in combination with other workplace exposures, the general environment, or with medications or personal habits of the worker to produce health effects even if the occupational exposures are controlled at the limit set by the criterion. These combined effects are often not considered in the evaluation criteria. Also, some substances are absorbed by direct contact with the skin and mucous membranes, which may increase the overall exposure. Finally, evaluation criteria may change over the years as new information on the toxic effects of an agent become available.

The primary sources of environmental evaluation criteria for the workplace are the following: (1) NIOSH RELs, (2) the ACGIH TLVs, and (3) the OSHA PELs. The OSHA PELs may be required to take into account the feasibility of controlling exposures in various industries where the agents are used; the NIOSH RELs, by contrast, are based primarily on
concerns relating to the prevention of occupational disease. In evaluating the exposure concentrations and the recommendations for reducing these concentrations found in this report, it should be noted that the lowest exposure criteria was used; however, industry is legally required to meet those limits specified by the OSHA standard.

A time-weighted average (TWA) exposure refers to the average airborne concentration of a substance during a normal 8- to 10-hour workday. Some substances have recommended short-term exposure limits (STELs) or ceiling values which are intended to supplement the TWA where there are recognized toxic effects from high short-term exposures.

INDUSTRIAL HYGIENE CRITERIA

Acrolein, acetaldehyde, and formaldehyde were not constituents of the glycol solutions used to generate theatrical "smoke." However, they are potential decomposition products from heated glycol solutions, and so they are discussed below.

**Acrolein**

Acrolein is a very intense irritant, causing rapid injury to the respiratory tract, eyes, and skin. The irritation threshold in humans is 0.25 parts per million (ppm) for all mucous membranes. Due to its strong lachrymatory (watering of the eyes) effect, acrolein does offer good warning properties. While skin contact with the vapor or liquid can cause severe burns, inhalation is the most serious hazard. Chronic toxicity has not been shown with this compound, but dermatitis and skin sensitization have been observed.

While the carcinogenic potential of acrolein has not been adequately determined, one of its potential metabolites (glycidaldehyde) is considered to be carcinogenic. The OSHA PEL, NIOSH REL, and ACGIH TLV for acrolein is 0.1 ppm for up to a 10-hour TWA.

**Acetaldehyde**

Acetaldehyde, also an irritant of the mucous membranes at low concentrations, may cause dermatitis and conjunctivitis following repeated exposures to the liquid or vapors. In studies assessing human effects, volunteers who were exposed for 15 minutes to 50 ppm of acetaldehyde experienced mild irritation. In more sensitive human subjects, however, irritation was noted at concentrations of 25 ppm. Generally, the fruity odor of acetaldehyde offers good warning properties.

The OSHA PEL and ACGIH TLV for acetaldehyde is 100 ppm, TWA for an 8- to 10-hour exposure. The International Agency for Research on Cancer (IARC) has concluded that there is sufficient evidence for the carcinogenicity of acetaldehyde in animals but inadequate evidence for carcinogenicity in humans. NIOSH considers that, in the absence of adequate
data on humans, it is reasonable to regard chemicals for which there is sufficient evidence of carcinogenicity in animals as if they present a carcinogenic risk to humans. Since acetaldehyde is an animal carcinogen and, therefore, a potential occupational carcinogen, the NIOSH policy is to reduce exposure to the lowest feasible limit.\textsuperscript{12}

**Formaldehyde**

Exposures to low concentrations of formaldehyde vapor will cause irritation of the eyes and respiratory tract. Because it is readily soluble in water, most of the irritant effects are restricted to the upper respiratory tract where the chemical is quickly absorbed. A concentration of 2 to 3 ppm will cause formication (a term describing the sensation of small insects crawling on the skin) of the eyes, nose, and throat.\textsuperscript{9} Ten ppm is tolerated with difficulty by most people for only a short period of time.\textsuperscript{9}

Some people may be especially sensitive to formaldehyde and can become symptomatic at concentrations well below 1 ppm. Case reports of asthma apparently induced by formaldehyde have been reported, although a true immunologically mediated allergic response has not been documented.\textsuperscript{2,13,14} Formaldehyde has been shown to be carcinogenic in several animal studies.\textsuperscript{9} Some research suggests that the potential carcinogenic effects of formaldehyde is particularly enhanced in the presence of hydrochloric acid vapors.\textsuperscript{15}

The OSHA PEL for formaldehyde is 0.75 ppm, TWA over an 8-hour work day with a STEL of 2 ppm.\textsuperscript{c} NIOSH recommends that formaldehyde be treated as a potential occupational carcinogen and recommends that exposures be kept as low as feasible.\textsuperscript{16} The ACGIH TLV is 1 ppm, TWA over an 8-hour work day.

**Mineral Oil**

Also termed liquid paraffin and white mineral oil, this hydrocarbon mixture is produced by removing the lighter hydrocarbons from petroleum by distillation, followed by charcoal filtering and additional distillation steps.\textsuperscript{17} The final product is colorless, tasteless, and generally odorless (when cold). Mineral oil is used in drugs applied to the nasal membranes and as a laxative. It is used as a solvent for inks in the printing industry and as a general lubricant.\textsuperscript{9}

Mineral oil mist is considered to have low toxicity. The IARC has determined that there is no evidence that the fully solvent refined oils are carcinogenic to experimental animals in either skin painting or feeding studies.\textsuperscript{18} However, the IARC has determined that, based on epidemiologic studies, there is sufficient evidence for carcinogenicity in humans of

\textsuperscript{c} ACGIH considers formaldehyde to be a suspect human carcinogen and has proposed to reduce the TLV to 0.3 ppm as a ceiling limit which should not be exceeded.
uncharacterized mineral oils containing additives and impurities. Fortunately, most of the mineral oils in use today are free of additives and impurities because of improvements in the refining process.

In a study of mineral oil mist exposures in machine shops where the average airborne concentration was 3.7 mg/m³ (the maximum short-term concentration measured was 110 mg/m³), no increase in respiratory symptoms or decrement in respiratory performance was observed in the employees. There have been no reported cases of illnesses in other studies, in a variety of industries, of human exposures to mineral oil mist concentrations which averaged less than 15 mg/m³.

The OSHA PEL, NIOSH REL, and ACGIH TLV for mineral oil mist is 5 mg/m³, TWA for up to a 10-hour exposure. The OSHA and NIOSH STEL for mineral oil mist is 10 mg/m³.

**Glycols**

None of the glycols identified in the bulk samples of the fog solutions used in the Broadway plays surveyed have been found to be mutagenic or carcinogenic. Table 2 lists the major glycols identified in these fluids and describes their health effects.

Since glycols are polyfunctional alcohols, exposures to any of these substances may cause a drying of exposed mucous membranes, resulting in dry, irritated eyes and respiratory tract irritation. Some studies have reported that ethylene glycol and diethylene glycol have had embryo-toxic effects in some test animal species; both have other harmful health effects (e.g., kidney or liver damage) if significant amounts are ingested. Other studies, involving human as well as animal subjects, have shown ethylene glycol to cause upper respiratory irritation, although the airborne concentrations necessary to achieve these irritant effects have varied greatly. In one of these studies, the test subjects were exposed for 20 to 22 hours/day to average concentrations which exceeded 30 milligrams of ethylene glycol per cubic meter of air.

The OSHA PEL for ethylene glycol is 127 mg/m³. This is a ceiling limit which should not be exceeded at any time during the work day. There is no NIOSH REL for ethylene glycol; however, because of the potential teratogenicity and the known respiratory irritation at the level chosen for the OSHA PEL, NIOSH has suggested that OSHA reconsider their current PEL for ethylene glycol. The ACGIH TLV for ethylene glycol is a ceiling limit of 125 mg/m³ (a level which should not be exceeded at any time during the work day). Ethylene glycol is also under study by the ACGIH TLV Committee. There are no OSHA, NIOSH, or ACGIH exposure criteria for the other glycols.

**Volatile Organic Compounds**
Volatile organic compounds (VOCs) describe a large class of chemicals which are organic (i.e., containing carbon) and have a sufficiently high vapor pressure to allow some of the compound to exist in the gaseous state at room temperature. These compounds are emitted in varying concentrations from numerous indoor sources including, but not limited to, carpeting, fabrics, adhesives, solvents, paints, cleaners, waxes, cigarettes, and combustion sources.

Studies have measured wide ranges of VOC concentrations in indoor air as well as differences in the mixtures of chemicals which are present. Research also suggests that the irritant potency of these VOC mixtures can vary. Although in some instances it may be useful to identify some of the individual chemicals which may be present, the concept of total volatile organic compounds (TVOC) has been used in an attempt to predict certain types of health effects. The use of this TVOC indicator, however, has never been standardized. Some researchers have compared levels of TVOCs with human responses (such as headache and irritative symptoms of the eyes, nose, and throat). However, neither NIOSH nor OSHA currently have specific exposure criteria for VOC mixtures in the nonindustrial environment.

**RESULTS**

**INDUSTRIAL HYGIENE**

**Bulk Sample Analysis**

Analysis of the heated bulk samples revealed only the glycols which were expected (based on product information provided by the manufacturers). No decomposition products were detected. Two of the three samples contained propylene glycol, 1,3-butylene glycol, and triethylene glycol as the major components. The remaining bulk sample contained ethylene glycol and diethylene glycol as the major components, with trace amounts of triethylene glycol and propylene glycol.

**Air Monitoring Results**

**Glycols**

As shown in Table 3, ethylene glycol was measured in two of the three productions (*Phantom of the Opera* and *Miss Saigon*); however, these concentrations ranged from not detectable to 0.4 mg/m³, levels well below the OSHA PEL of 127 mg/m³. Propylene glycol was detected in samples from all three productions, ranging from <0.01 to 1.9 mg/m³. Triethylene glycol and 1,3-butylene glycol were detected only in *Les Miserables*, ranging from <0.04 to 3.7 mg/m³ and 0.16 to 2.1 mg/m³, respectively.
Formaldehyde/Aldehydes

As shown in Table 4, formaldehyde concentrations using NIOSH Sampling and Analytical Method 3500 (sodium bisulfite-filled impingers) ranged from <0.002 to 0.04 ppm. These concentrations are well below the OSHA and ACGIH exposure limits and are typical of concentrations which NIOSH investigators have measured in non-industrial workplaces. Acrolein was not detected on any of the GA samples (Minimum Detectable Concentration [MDC] = 0.016 mg/m$^3$).

Oil Mist

Only *Miss Saigon* used a mineral oil-based fog generation system. As shown in Table 5, all oil mist concentrations were less than 0.13 mg/m$^3$, amounts which are far below NIOSH, OSHA, and ACGIH exposure criteria of 5.0 mg/m$^3$ (TWA).

Volatile Organic Compounds

Copies of the reconstructed total ion chromatograms (with peak identification) from the analysis of the thermal desorption (TD) tube samples are shown in Figure 1. Only two of the TD samples (both obtained from the *Phantom of the Opera*—one at the Travelator [stage right] and the other from the orchestra pit) contained even modest concentrations; levels of compounds detected on all other samples were very low. Major compounds detected were mostly C$_9$-C$_{12}$ aliphatic hydrocarbons and C$_9$H$_{12}$ alkyl benzenes (trimethyl benzenes, propyl benzenes, etc.) Other compounds identified on these included 1,1,1 trichloroethane, acetaldehyde, acetone, isopropanol, toluene, limonene, siloxanes, and perchloroethylene. It should be noted that although thermal desorption is an extremely sensitive method, it is only qualitative.

**MEDICAL**

**Phase I: November 1993**

One hundred and thirty five (73%) of approximately 186 performers participated. This included three stage managers and several understudies. The show-specific participation rates are shown in Table 6. Of the 135 participants, 37 (27%) were symptomatic. All the symptomatic participants were recruited for Phase II. In addition, 68 asymptomatic performers (controls) were randomly selected for Phase II, making up a total Phase II study population of 105 performers.

**Phase II: November - December 1993**
Of the 105 participants, 65 (62%) submitted complete or partial information (peak flow measurements and questionnaires); 40 (38%) submitted no information. Two persons did not participate but gave their peak-flow meter and questionnaire to others (one to another performer, the other to a stage manager). The data from these two persons are not included in the analysis because they were not selected in the same manner as the other participants. (These persons would not have met the case definition.) The participation rate for symptomatic persons was 57% (21/37); the participation rate for non-symptomatic persons was 65% (44/68). The show-specific participation rates are shown in Table 7.

A total of five persons met the above case definition for asthma. Three worked in "smoke"-using productions and two did not. Of the 60 persons who did not meet the case definition, 16 had been identified as being "symptomatic" in the Phase I portion of the evaluation, and were therefore excluded from further analysis. This left 45 non-case performers; 27 of these were "smoke"-exposed and 18 were not. The odds ratio (OR) for the association between being a case and being "smoke"-exposed was 1.0 (95% confidence interval [CI] = 0.1-13.1). (See Table 8.)

**DISCUSSION**

**INDUSTRIAL HYGIENE**

All of the GA sample results were well below available exposure criteria. Except for ethylene glycol, however, none of the glycols measured in this study have OSHA, NIOSH, or ACGIH exposure criteria. One of the three bulk samples of glycol-based fog fluids contained ethylene glycol and diethylene glycol as major components (with trace amounts of triethylene glycol and propanetriol). Although these two glycols are not exceptionally toxic when compared to many chemicals, the glycols which were identified in the other two bulk samples (primarily propylene, triethylene, or 1,3 butylene glycols) would be less toxic substitutes.

No decomposition products were observed either in the headspace analysis of the heated bulk samples or in the field samples collected in this follow-up survey. However, in the initial 1991 survey, decomposition products (such as acrolein and acetaldehyde) were detected by NIOSH in a laboratory setting when a glycol-based fog solution was heated to approximately 700°F. (One of the fog systems in use during the 1991 survey heated the fluid to this temperature.) It should be noted that these decomposition products were not detected in PBZ and GA air samples collected during the play in which this fog system was used. Regardless, it would still appear to be prudent to use glycol-based fog systems which are designed to operate at the lowest temperature consistent with proper aerosolization. NIOSH investigators are aware of fog systems which do not heat their glycol fluid beyond 500°F.
The finding of an OR of 1.0 (CI = 0.1 - 13.1) indicates that performers with asthma-like symptoms and measurable bronchial lability were not more likely to have been exposed to theatrical "smoke" when compared to persons who did not meet this case definition.

There are a number of reasons for finding potential cases of asthma but not finding a significant association between these cases and exposure to theatrical "smoke" in this study. First, theatrical "smoke" may not cause asthma. Second, various occupational and non-occupational conditions can affect PEFR and other measures of pulmonary function. Cigarette-related bronchitis is one of the most common causes of pulmonary function abnormalities among the working population; certain occupational chemical and dust exposures can also cause or contribute to it. Exercise and underlying lung disease may also be expected to produce abnormal pulmonary function tests. Further, asthma is a difficult disease to diagnose; there are no widely accepted criteria by which to reliably establish the diagnosis of asthma. Pulmonary function testing, using such tools as peak-flow meters, along with questionnaire data, have been used in other studies to find potential cases of asthma. However, these methods have limitations. Peak-flow meters are subject to variation based on the meter itself as well as the effort of the operator. In addition, questionnaire data may not accurately reflect the symptoms or medical history of the participants.

Finally, it is important to note the low response rate (62%) for Phase II. This limits our ability to detect differences between "smoke"-exposed and non-"smoke"-exposed performers and diminishes the reliability of the conclusions drawn from these data.

**CONCLUSIONS**

The HHE request was submitted because of the performers' concern about the acute and possible chronic effects of exposure to theatrical "smoke." Based on the results of this study, there is no evidence that theatrical "smoke," at the levels found in the theaters studied, is a cause of occupational asthma among performers.

Nevertheless, some of the constituents of theatrical "smoke" (such as the glycols) have irritative and mucous membrane drying properties. It would therefore be reasonable to modify the factors which may influence a performer's exposure to the "smoke."

**RECOMMENDATIONS**

Some of the air sampling data collected during the initial 1991 NIOSH survey (see Appendix A) suggests that short-term "peak" exposures to theatrical "smoke" may occur throughout any performance, coinciding with the "smoke" cues for that particular
production. These peak exposures may be sufficiently high to contribute to the work-related irritation reported by some of the actors. "Smoke" machines should therefore be located so as to minimize actors' exposure to the concentrated aerosol as it first exits the machine. The quantity and frequency of use of the various fogs during a performance should be minimized.

Comments:

1. Laboratory analysis revealed the presence of some of the higher molecular weight glycols (tetraethylene, pentaethylene, hexaethylene, etc.). These compounds, which were present in trace amounts, are not discussed in this table.
2. Except as otherwise noted, the information presented in this table was obtained from the following sources: Patty's Industrial Hygiene and Toxicology; Procter, Hughes and Fischman Chemical Hazards of the Workplace; and the American Conference of Governmental Industrial Hygienists' Documentation of the Threshold Limit Values and Biological Exposure Indices.

Evaluation Criteria: (in milligrams per cubic meter)

- OSHA PEL (Ceiling limit)
- ACGIH TLV (Ceiling limit)
- NIOSH REL

Comments and Footnotes:

- **a** = There is no NIOSH REL for ethylene glycol. However, because of the potential teratogenicity and the known respiratory irritation at the level adopted for the OSHA PEL, NIOSH suggests that OSHA reconsider their current PEL for ethylene glycol.
- Trace = Concentration is between the minimum detectable and minimum quantifiable concentration for this sample set.
- ND = Not detectable (below the minimum detectable concentration).

Comments and Abbreviations:
General area air samples for formaldehyde collected following NIOSH Sampling and Analytical Method 3500 (impingers filled with 1% sodium bisulfite solution). This method offers the best sensitivity for formaldehyde.
‡ NIOSH considers formaldehyde a suspect human carcinogen and recommends that exposures be kept as low as feasible.
TWA = time weighted average
STEL = short-term exposure limit (15 minutes)
Trace = Concentration is between the Minimum Detectable and Minimum Quantifiable Concentration.

**COMMENTS AND ABBREVIATIONS:**

\(^a\) = All oil mist concentrations are time-weighted averages over the time period sampled and are expressed in milligrams of oil mist per cubic meter of air.

Trace = These concentrations are between the minimum detectable and minimum quantifiable concentration for this sample set. This means that oil mist was detectable but could not be reliably measured.

TWA = Time-weighted average exposure

**SUMMARY**

In July and August, 1990 the National Institute for Occupational Safety and Health (NIOSH) received requests from the Actors’ Equity Association (AEA) and the League of American Theatres and Producers, Inc. to investigate possible health effects associated with the use of theatrical "smokes" in Broadway productions.

Four Broadway productions (LES MISERABLES, MISS SAIGON, PHANTOM OF THE OPERA, AND GRAND HOTEL) which used theatrical smoke were selected and dress rehearsals were arranged to conduct personal breathing-zone (PBZ) and general area (GA) air sampling and to administer a questionnaire to the actors detailing the frequency and severity of irritant and respiratory symptoms (if any) when exposed to theatrical smoke. A small number of PBZ air samples were collected on electricians, carpenters, and other personnel who may have been exposed to the theatrical smoke during a performance. To determine if the prevalence of symptoms among actors in shows using theatrical smoke(s) differed from the symptom prevalence in non-smoke productions, NIOSH investigators also administered the same questionnaire to actors in five Broadway productions in which no theatrical smoke was used (LOST IN YONKERS, GYPSY, GETTING MARRIED, ONCE ON THIS ISLAND, AND SIX DEGREES OF SEPARATION). The actors in these non-smoke productions are termed "controls" in this report.

Air sampling at the smoke productions was completed during dress rehearsals held between June 17 and July 2, 1991. Questionnaires were administered during this same time period to all of the selected Broadway productions. Although theatrical smoke was visibly evident during all of the performances, results from all of the PBZ and GA air samples collected were very low when compared to applicable Occupational Safety and Health Administration (OSHA) Permissible Exposure Limits (PELs), American Conference of Governmental Industrial Hygienists (ACGIH) Threshold Limit Values (TLVs), or NIOSH Recommended Exposure Limits (RELs). For example, acrolein and acetaldehyde, suspected to be possible decomposition products from the heating of the glycol-based fog fluids, were not found on any of the PBZ or GA air samples collected during this survey. None of the PBZ air samples had detectable amounts of formaldehyde.

Only 21 of the 120 PBZ and GA air samples collected for glycols (specifically ethylene, propylene, 1,3 butylene, diethylene, and triethylene glycols) during this investigation had detectable amounts of these substances. Excluding the results obtained from two GA air samples situated directly adjacent to the on-stage smoke machines used in LES MISERABLES, all of the remaining glycol concentrations were extremely low, ranging up to 2.1 milligrams per cubic meter (mg/m$^3$). These concentrations were well below the OSHA PEL for ethylene glycol of 127 mg/m$^3$ (short-term exposure limit of 15 minutes). There is no NIOSH REL for ethylene glycol; however, because of the potential teratogenicity and the

NIOSH Sampling and Analytical Method No. 5500 was developed for ethylene glycol alone. NIOSH investigators have recently determined that this method may have deficiencies when used to identify and quantitate other similar glycols as were encountered in this evaluation (such as propylene, butylene, diethylene, and triethylene glycols). In at least one instance ethylene glycol was incorrectly identified in an air sample. Since it is possible that interferences from other glycol analytes may have occurred, only qualitative glycol sampling data will be discussed in the final report. The sections of this revised interim report affected by these analytical problems have been highlighted. A thorough discussion of the analytical problems encountered while using NIOSH Sampling and Analytical Method 5500 for these glycols will be contained in the final report.
NIOSH Sampling and Analytical Method No. 5500 was developed for ethylene glycol alone. NIOSH investigators have recently determined that this method may have deficiencies when used to identify and quantitate other similar glycols as were encountered in this evaluation (such as propylene, butylene, diethylene, and triethylene glycols). In at least one instance ethylene glycol was incorrectly identified in an air sample. Since it is possible that interferences from other glycol analytes may have occurred, only qualitative glycol sampling data will be discussed in the final report. The sections of this revised interim report affected by these analytical problems have been highlighted. A thorough discussion of the analytical problems encountered while using NIOSH Sampling and Analytical Method 5500 for these glycols will be contained in the final report.

Air samples (both PBZ and GA) were collected for mineral oil mist during a dress rehearsal of MISS SAIGON. Concentrations ranged up to 1.35 mg/m³, TWA over duration of the play. The highest levels were measured in GA samples positioned on stage. All of the measured concentrations were well below the OSHA, NIOSH, and ACGIH exposure limits of 5 mg/m³ for up to a full-shift (8 to 10 hours) TWA exposure.

All 224 actors from nine Broadway productions completed questionnaires. Of this group, 134 questionnaires (60%) were from actors appearing in the four productions using theatrical smokes, and 90 questionnaires (40%) were from actors appearing in the five control productions.

When compared to actors from the non-smoke productions, actors from two or more of the four productions utilizing theatrical smoke reported experiencing significantly greater prevalence of nasal symptoms (sneezing, runny or stuffy nose), respiratory symptoms (cough, wheeze, breathlessness, chest tightness), and mucous membrane symptoms (sore throat, hoarseness, dry throat, itchy, burning eyes, dry eyes) during their performances for the week prior to the survey. Although some of the constituents of theatrical smoke (primarily the glycols) have irritative properties, the reason for the high symptom prevalence in the productions that use theatrical smoke is not clear, since the time-weighted average concentrations of the glycols measured during the performances were quite low. It is possible however, that the smoke concentrations could be sufficiently high during the short periods of time that the smoke is generated to contribute to the symptoms reported by the actors.

While some mucous membrane irritative symptoms (eyes, nose, throat) might be expected, the high prevalence of work related lower respiratory symptoms (cough, wheeze, chest tightness, and shortness of breath) reported by the smoke-exposed actors was surprising. It is possible that the questionnaire was too sensitive in its design and caused an over-reporting of symptoms, the constituents of theatrical smoke may be more irritative at low concentrations than previously documented, or there may be other factors involved. Since the etiology is unclear at this time, a return visit is planned to gather further information on the nature of these symptoms.

In this interim period, the NIOSH investigators recommend that only smoke fluids which are approved by the manufacturers be used. For the glycols which are used, their purity should be at the level of “food grade” or "high grade" to minimize the presence of impurities. Relocating the smoke machine(s) (either glycol or mineral oil-based) to avoid exposing actors...
NIOSH Sampling and Analytical Method No. 5500 was developed for ethylene glycol alone. NIOSH investigators have recently determined that this method may have deficiencies when used to identify and quantitate other similar glycols as were encountered in this evaluation (such as propylene, butylene, diethylene, and triethylene glycols). In at least one instance ethylene glycol was incorrectly identified in an air sample. Since it is possible that interferences from other glycol analytes may have occurred, only qualitative glycol sampling data will be discussed in the final report. INTRODUCTION

In July 1990, the National Institute for Occupational Safety and Health (NIOSH) received a request from the Actors’ Equity Association (AEA) for a series of health hazard evaluations (HHE) to investigate possible health effects associated with the use of theatrical "smokes" in Broadway productions. A similar request was received from the League of American Theatres and Producers, Inc. Both requests have been combined into this interim report.

On January 9-10, 1991, NIOSH investigators conducted an initial site visit to investigate the possibility of conducting industrial hygiene and medical surveys on Broadway actors exposed to the various theatrical fogs used during specific productions. The opening conference was attended by representatives from AEA, the League of American Theatres and Producers, the various Broadway productions that utilized the fogs, and private industrial hygiene consulting firms. This initial conference covered the NIOSH HHE program and the scope and purpose of the evaluation.

BACKGROUND

Many of the theatrical smokes currently in use in Broadway theaters, in television, and in motion pictures utilize heated glycol fluids to produce a visible aerosol. While the exact formulations of these fluids are considered proprietary by the manufacturers, some of the more commonly used glycols include ethylene glycol; propylene glycol; 1,3 butylene glycol; diethylene glycol; and triethylene glycol. Some of the higher molecular weight glycol compounds, such as tetra-, penta-, hexa-, and heptaethylene glycols, may also be used. All four of the "smoke" productions included in this survey used a glycol-based smoke generation system. Sizes of the glycol-based smoke systems ranged from larger units (permanently mounted either on or off stage) to smaller, hand-held devices operated by stage hands during a performance. In one of the Broadway productions (MISS SAIGON) an unheated mineral oil-based smoke generation system was also used. Table 1 summarizes the brands of smoke producing systems in use during this evaluation and where they were used.

\[d\] In addition to the glycol-based smoke systems, some of the productions used dry ice (carbon dioxide) fog systems.
EVALUATION DESIGN AND METHODS

Four Broadway productions (LES MISERABLES, MISS SAIGON, GRAND HOTEL, AND PHANTOM OF THE OPERA) were selected for studying actor's exposures to theatrical smoke. With the cooperation of the AEA and the League of American Theatres and Producers, special dress rehearsals were arranged with each production company to allow NIOSH investigators to conduct personal breathing-zone (PBZ) and general area (GA) air sampling during the performance of the play and also to administer a questionnaire to the actors. In addition to the performers, a small number of PBZ air samples were collected on electricians, carpenters, and other personnel who may have been exposed to the theatrical smoke during a performance.

All four of the "smoke" productions, LES MISERABLES, MISS SAIGON, GRAND HOTEL, AND PHANTOM OF THE OPERA, were previewed by NIOSH investigators prior to conducting the air sampling and administering the symptoms questionnaire. This was to acquaint the investigators with the smoke cues, meet with the production managers and actors, and to select sites for GA samples. The air sampling strategy was to collect the PBZ and GA air samples during the play with minimal disruptions. With the exceptions of the actors not being in full costume and the orchestra being absent (background music provided from tape and/or piano), everything in these dress rehearsals was conducted (including smoke cues and any other special effects) as if they were actual performances before an audience.

The four dress rehearsals, along with the theater where the play was performed, were scheduled as follows.

- June 18, 1991 - PHANTOM OF THE OPERA (Majestic Theatre)
- June 20, 1991 - GRAND HOTEL (Martin Beck Theatre)
- June 25, 1991 - MISS SAIGON (first time) (Broadway Theatre)
- July 2, 1991 - LES MISERABLES (Imperial Theatre)
- July 2, 1991 - MISS SAIGON (second time) (Broadway Theatre)

In all of these productions the use of theatrical smokes (either glycol, mineral oil, or carbon dioxide-based) were precisely timed. A list of smoke cues was provided by the production managers prior to the dress rehearsals to help in selecting the appropriate actors and stage

\(^{c}\) Short-term GA and PBZ air samples were collected for glycols and formaldehyde in PHANTOM OF THE OPERA and GRAND HOTEL.

\(^{f}\) Personal and general area air samples were collected during the dress rehearsal of MISS SAIGON on June 25, 1991. General area air samples (both on-stage and off-stage) were collected during a live evening performance on July 2, 1991.
locations to sample. A smoke cue would prompt the stage electrician (or whoever was in charge of operating the smoke machines) to provide a specific amount of smoke. The quantity of smoke was determined by controlling the time the smoke machine ran (typically 5 to 10 seconds). Some leeway was given to the person controlling the smoke based on whether the necessary visual appearance was achieved on stage. If the smoke effects were not sufficient, the play's director would ask the smoke controller to provide additional smoke. It was apparent from watching the actual performances and the dress rehearsals that it was seldom necessary for the stage crew controlling the smoke machines to deviate from the established cue times.

Based simply on visual observations, the quantities of smoke varied greatly between each of the four plays. For example, in *GRAND HOTEL* the glycol-based smoke machines operated before the play actually began in order to create the required "smokey" ambience over the entire stage. The smoke machines, however, were not used again until a train scene which occurred late in the play. For comparison, *MISS SAIGON* used glycol and mineral oil-based smoke systems throughout the play to create the desired atmosphere of wartime Saigon and Bangkok, where the play was situated.

Using visual observations, NIOSH investigators qualitatively ranked the four productions in the following order on the amount of smoke used during the performance. Cigarette smoking was minimal during all except *GRAND HOTEL*, a play in which the actors were required to smoke during several scenes.

**BULK SAMPLE ANALYSIS**

Four bulk samples of fluids used in theatrical fog-generating machines were submitted for laboratory analysis. Three of the bulks (the glycol-containing solutions) were heated to
specified temperatures (ranging from 290 to 370°C) and the effluent analyzed for volatile organic compounds by gas chromatography-mass spectrophotometry (GC-MS). All of the bulk solutions were also analyzed directly for major constituents.

WORKPLACE AIR MONITORING

PBZ and GA air sampling was performed for a variety of substances. Most of the glycols which were analyzed for, including propylene, ethylene, diethylene, triethylene, tetraethylene, and 1,3 butylene glycols, were present in the bulk samples of the theatrical smoke fluids. Air samples were collected for aldehydes (specifically acetaldehyde, formaldehyde, and acrolein). These were considered by NIOSH investigators to be the most likely decomposition products from the heating of the glycol solutions. Samples were also collected for mineral oil mist during a performance of MISS SAIGON.

Table 2 summarizes the methods used to collect and analyze the PBZ and GA air samples. The air sampling was generally conducted for the length of each performance (approximately two hours for all but LES MISERABLES, which exceeded three hours). Most of the actors wore one sampling pump during the play. However, some principal actors were required to wear two sampling pumps if they were on stage during the scenes in which theatrical smoke was used. The air sampling was conducted so as to cause minimal disruptions during each dress rehearsal. One exception was the collection of three short-term GA air samples during the magic mirror/dressing room scene in PHANTOM OF THE OPERA; this procedure required the actors to stop for approximately five minutes. The collection of three short-term GA air samples during GRAND HOTEL, however, did not disrupt the flow of the play.

MEDICAL EVALUATION

A questionnaire detailing the frequency and severity of irritant and respiratory symptoms experienced during performances the week prior to the survey was administered to actors exposed to theatrical smoke in four Broadway productions. To determine if the prevalence of symptoms among actors in shows using theatrical smokes differed from the prevalence in productions not using smoke, the same questionnaire was administered to actors in five
Broadway productions (*LOST IN YONKERS, GYPSY, GETTING MARRIED, ONCE ON THIS ISLAND, AND SIX DEGREES OF SEPARATION*) in which no theatrical smoke was used; these participants served as controls.

Each actor was asked to respond to background questions concerning age, length of time as a professional actor, length of time spent on stage in the current production, smoking status, and specific questions about his or her present state of health. Each actor was also asked whether or not he or she had experienced any of a list of 17 irritant and respiratory symptoms during performances the previous week. Participants were then asked to rate the frequency (never, rarely, sometimes, often, always) and severity (1-mild to 5-severe) of each symptom. Symptoms were then divided into an upper respiratory tract symptom group (stuffy nose, sneezing, coughing, sore throat, and dry throat), a lower respiratory tract symptom group (wheezing, shortness of breath, and chest tightness), and an eye symptom group (dry eyes, sore/itchy/watery eyes, and burning eyes). If a participant reported experiencing two or more of a group's symptoms "sometimes," "often," or "always," we considered that group's symptoms to be present. The prevalence of such positive responses among actors in smoke-utilizing productions was then compared to those among actors in control (non-smoke-utilizing) productions.

Actors in each production were asked if they usually had a cough which produced phlegm as much as twice per day, four or more days of the week. (Duration of the phlegm production was not asked.) Those answering yes to these criteria were considered (for the purposes of this evaluation) to have symptoms compatible with chronic bronchitis. Since cigarette smoking can cause chronic bronchitis, (and would therefore be a confounder in the analysis) we eliminated smokers from the analysis of chronic bronchitis.

**EVALUATION CRITERIA**

**GENERAL**

As a guide to the evaluation of the hazards posed by workplace exposures, NIOSH field staff employ environmental evaluation criteria for the assessment of a number of chemical and physical agents. These criteria are intended to suggest limits of exposure to which most workers may be exposed up to 10 hours per day, 40 hours per week for a working lifetime without experiencing adverse health effects. It is, however, important to note that not all workers will be protected from adverse health effects even though their exposures are maintained below these limits. A small percentage may experience adverse health effects because of individual susceptibility, a pre-existing medical condition, and/or a hypersensitivity (allergy). In addition, some hazardous substances may act in combination with other workplace exposures, the general environment, or with medications or personal habits of the worker to produce
health effects even if the occupational exposures are controlled at the limit set by the criterion. These combined effects are often not considered in the evaluation criteria. Also, some substances are absorbed by direct contact with the skin and mucous membranes, and thus potentially increase the overall exposure. Finally, evaluation criteria may change over the years as new information on the toxic effects of an agent become available.

The primary sources of environmental evaluation criteria for the workplace are the following: 1) NIOSH Recommended Exposure Limits (RELs),\(^2\) 2) the American Conference of Governmental Industrial Hygienists' (ACGIH) Threshold Limit Values (TLVs),\(^3\) and 3) the U.S. Department of Labor, Occupational Safety and Health Administration (OSHA) Permissible Exposure Limits (PELs)\(^4\). The OSHA PELs may be required to take into account the feasibility of controlling exposures in various industries where the agents are used; the NIOSH RELs, by contrast, are based primarily on concerns relating to the prevention of occupational disease. In evaluating the exposure concentrations and the recommendations for reducing these concentrations found in this report, it should be noted that the lowest exposure criteria was used; however, industry is legally required to meet those limits specified by the OSHA standard.

A time-weighted average (TWA) exposure refers to the average airborne concentration of a substance during a normal eight- to ten-hour workday. Some substances have recommended short-term exposure limits (STELs) or ceiling values which are intended to supplement the TWA where there are recognized toxic effects from high short-term exposures.

**SPECIFIC SUBSTANCES**

Acrolein, acetaldehyde, and formaldehyde were not constituents of the glycol solutions used to generate theatrical smoke. However, they are potential decomposition products from heated glycol solutions, so they are discussed below.

**Acrolein**

Acrolein is a very intense irritant, causing rapid injury to the respiratory tract, eyes, and skin. The irritation threshold in humans is 0.25 parts per million (ppm) for all mucous membranes.\(^5\) Due to its strong lacrimation (watering of the eyes) effect, acrolein does offer good warning properties. While skin contact with the vapor or liquid can cause severe burns, inhalation is the most serious hazard. Chronic toxicity has not been shown with this compound, but dermatitis and skin sensitization has been observed.

While the carcinogenic potential of acrolein has not been adequately determined, one of its potential metabolites (glycidaldehyde) is considered to be carcinogenic.\(^6,7\) The OSHA PEL, NIOSH REL, and ACGIH TLV for acrolein is
0.1 ppm for up to a 10-hour TWA.

**Acetaldehyde**

Acetaldehyde, also an irritant of the mucous membranes at low concentrations, may cause dermatitis and conjunctivitis following repeated exposures to the liquid or vapors. In studies assessing human effects, volunteers who were exposed for 15 minutes to 50 ppm of acetaldehyde experienced mild irritation. In more sensitive human subjects, however, irritation was noted at concentrations of 25 ppm. Generally the fruity odor of acetaldehyde offers good warning properties.

The OSHA PEL and ACGIH TLV for acetaldehyde is 100 ppm, TWA for an eight to ten hour exposure. The International Agency for Research on Cancer (IARC) has concluded that there is sufficient evidence for the carcinogenicity of acetaldehyde in animals but inadequate evidence for carcinogenicity in humans. NIOSH considers that, in the absence of adequate data on humans, it is reasonable to regard chemicals for which there is sufficient evidence of carcinogenicity in animals as if they presented a carcinogenic risk to humans. Since acetaldehyde is an animal carcinogen and, therefore, a potential occupational carcinogen, the NIOSH policy is to reduce exposure to the lowest feasible limit.

**Formaldehyde**

Exposures to low concentrations of formaldehyde vapor will cause irritation of the eyes and respiratory tract. Because it is readily soluble in water, most of the irritant effects are restricted to the upper respiratory tract where the chemical is quickly absorbed. A concentration of two to three ppm will cause formication (a term describing the sensation of small insects crawling on the skin) of the eyes, nose, and throat. Ten ppm is tolerated with difficulty by most people for only a short period of time.

Some people may be especially sensitive to formaldehyde and can become symptomatic at concentrations well below one ppm. Case reports of asthma apparently induced by formaldehyde have been reported, although a true immunologically mediated allergic response has not been documented. Formaldehyde has been shown to be carcinogenic in several animal studies. A large historic cohort study of industrial workers with exposure to formaldehyde did not identify any excesses of leukemia, brain cancer, or nasal cancer. Some research suggests that the potential carcinogenic effects of formaldehyde is particularly enhanced in the presence of hydrochloric acid vapors.
The OSHA PEL and ACGIH TLV for formaldehyde is one ppm, TWA over an eight-hour work day with a short-term exposure limit of two ppm.\(^h\) NIOSH recommends that formaldehyde be treated as a potential occupational carcinogen and recommends that exposures be kept as low as feasible. This is based on the mutagenic activity formaldehyde has shown in several test systems and that it has induced nasal cancer in rats and mice.\(^{14}\)

Mineral Oil

Also termed liquid paraffin and white mineral oil, this hydrocarbon mixture is produced by removing the lighter hydrocarbons from petroleum by distillation, followed by charcoal filtering and additional distillation steps.\(^{15}\) The final product is colorless, tasteless, and generally odorless (when cold). Mineral oil is used in drugs applied to the nasal membranes and as a laxative. It is used as a solvent for inks in the printing industry and as a general lubricant.\(^5\)

Mineral oil mist is considered to have low toxicity. The IARC has determined that there is no evidence that the fully solvent refined oils are carcinogenic to experimental animals in either skin painting or feeding studies.\(^{16}\) However, the IARC has determined that, based on epidemiologic studies, there is sufficient evidence for carcinogenicity in humans of uncharacterized mineral oils containing additives and impurities.\(^{16}\) Fortunately, most of the mineral oils in use today are free of additives and impurities because of improvements in the refining process.\(^{17}\)

In a study of mineral oil mist exposures in machine shops where the average airborne concentration was 3.7 mg/m\(^3\) (the maximum short-term concentration measured was 110 mg/m\(^3\)), no increase in respiratory symptoms or decrement in respiratory performance was observed in the employees.\(^{18}\) There have been no reported cases of illnesses in other studies which covered a variety of industries and involved human exposures to mineral oil mist concentrations which averaged less than 15 mg/m\(^3\).\(^{19}\)

The OSHA PEL, NIOSH REL, and ACGIH TLV for mineral oil mist is 5 mg/m\(^3\), TWA for up to a ten-hour exposure. The OSHA and NIOSH short-term exposure limit for mineral oil mist 10 mg/m\(^3\).

Glycols

---

\(^h\) ACGIH considers formaldehyde to be a suspect human carcinogen and has proposed to reduce the TLV to 0.3 ppm as a ceiling limit which should not be exceeded.
None of the glycols identified in the bulk samples of the fog solutions used in the Broadway plays surveyed have been found to be mutagenic or carcinogenic. Table 3 lists the major glycols identified in these fluids and describes their health effects.

Since glycols are polyfunctional alcohols, exposures to any of these substances may cause a drying of exposed mucous membranes, resulting in dry, irritated eyes and respiratory tract irritation. Some recent studies have reported that ethylene glycol and diethylene glycol have had embryo-toxic effects in some test animal species; both have other harmful health effects (e.g., kidney or liver damage) if significant amounts are ingested. Other studies, involving human as well as animal subjects, have shown ethylene glycol to cause upper respiratory irritation, although the airborne concentrations necessary to achieve these irritant effects have varied greatly. In one of these studies the test subjects were exposed for 20 to 22 hours/day to average concentrations which exceeded 30 milligrams of ethylene glycol per cubic meter of air.

The OSHA PEL and ACGIH TLV (short-term exposure limits) for ethylene glycol is 127 mg/m³. There is no NIOSH REL for ethylene glycol; however, because of the potential teratogenicity and the known respiratory irritation at the level chosen for the OSHA PEL, NIOSH has suggested that OSHA reconsider their current PEL for ethylene glycol. There are no OSHA, NIOSH, or ACGIH exposure criteria for the other glycols.

RESULTS

BULK SAMPLES

Bulk samples from Rosco®, The Great American Market®, and Theater Magic® were qualitatively analyzed to identify major constituents. The fluids contained mixtures of several glycols, including ethylene, propylene, 1,3 butylene, and diethylene and triethylene glycols. In one bulk sample higher molecular weight glycol compounds (such as tetraethylene, pentaethylene, hexaethylene, and heptaethylene) may also have been present.

Headspace analysis by NIOSH chemists was also performed on the three glycol mixtures by heating them in a micro-combustion furnace to temperatures which approximated the temperatures to which the fluids were heated in the manufacturer's smoke generators. These temperatures ranged from 290° to 370°C. The effluent was then analyzed using charcoal and ORBO® 23 sorbent tubes for volatile organic compounds by GC-MS.

Analysis of the charcoal tube air samples collected from heated bulk samples of two of the three glycol fluids detected no decomposition compounds (with the exception of the
glycols previously identified in the unheated fluids). It should be noted that these samples were heated to either 290° or 315°C. In both cases, the non-volatility of the glycols and the fact that they condensed in the oven outlet prior to reaching the sorbent tubes contributed to the low concentrations measured.

Results of the qualitative headspace analysis from the third bulk glycol sample (a mixture which, according to the manufacturer, could be heated to a higher temperature [370°C, ≈700°F] to achieve a high quality of "smoke"), detected the presence of both acetaldehyde and formaldehyde. In addition, some acrolein and propanal was also detected. Although these results are only qualitative, the aldehydes as a group are skin, eye, and upper respiratory irritants. Their detection in the headspace analysis of the bulk sample heated to ≈700°F (but not in the glycol bulk samples heated to lower temperatures) may be significant in estimating the irritant potential of the theatrical smoke during actual use conditions.

AIR MONITORING

Considering that the vast majority of the PBZ and GA air samples collected in this evaluation had non-detectable (ND) amounts of the substances of interest, only those air samples which had detectable amounts are listed in the tables. Results from PBZ and GA air samples collected for glycols during this survey are shown in Table 4. The glycols detected included ethylene, propylene, 1,3 butylene, diethylene, and triethylene glycols. Ethylene glycol concentrations (the only glycol for which there are established exposure criteria) ranged from ND to 20.8 mg/m³, TWA.¹ All of the ethylene glycol levels measured are below the OSHA and ACGIH exposure criteria of 127 mg/m³ (for a 15 minute short-term exposure). As previously stated, there is no NIOSH REL for ethylene glycol. However, NIOSH has suggested that OSHA reconsider their current PEL for ethylene glycol.²⁴ There are no OSHA, NIOSH, or ACGIH exposure criteria for the other glycols.

¹ The highest measured ethylene glycol concentration came from an area air sample located directly adjacent to a smoke machine positioned on stage during LES MISERABLES. This level should not be considered representative of an actor's personal exposure.
As shown in Table 5, formaldehyde was detected in low concentrations in only a few GA air samples. Formaldehyde concentrations ranged up to 0.05 ppm, slightly above the ambient formaldehyde levels of 0.02 ppm measured outside two of the Broadway theaters. All of the formaldehyde concentrations were below applicable OSHA and ACGIH exposure criteria. NIOSH considers formaldehyde to be a suspect human carcinogen and recommends that exposures be kept to their lowest feasible levels. Acrolein and acetaldehyde (by-products produced by heating the glycol mixtures in the laboratory) were not detected on any of the air samples collected in the theaters during this study.

In addition to the glycol and aldehyde sampling, PBZ and GA air samples were collected for mineral oil mist during a dress rehearsal of MISS SAIGON. These concentrations, shown in Table 6, ranged from ND to 1.35 mg/m³, TWA over duration of the play (approximately 2.5 hours). The highest levels were measured in GA samples positioned on stage. All of the measured concentrations were well below the OSHA, NIOSH, and ACGIH exposure limits of 5 mg/m³ for up to a full-shift (8 to 10 hours) TWA exposure.

MEDICAL

All 224 actors from the nine Broadway productions completed questionnaires. Of this group, 134 questionnaires (60%) were from actors appearing in the four productions using theatrical smokes, and 90 questionnaires (40%) were from actors appearing in five control productions (Table 7).

Participants had a mean age of 34 (range 9 to 74 years), and had been professional actors for an average of 14 years (range 3 months to 45 years). The average length of time an actor had been a member of the cast was 14 months (range 1 to 52 months). Smoke-exposed actors and controls had a comparable distribution of ages, years as a professional actor, and number of months as a member of the cast (Table 8). Smoke-exposure productions, however, had a higher proportion of male actors than controls (62% vs. 54% respectively, p=0.057).

Responses of "sometimes," "often," or "always" to the occurrence during performances in the previous week of one or more irritant and/or respiratory symptoms among smoke

\footnote{Formaldehyde was only detected in GA air samples collected using the most sensitive method (sodium bisulfite-filled impingers, NIOSH method no. 3500).}

NIOSH Sampling and Analytical Method No. 5500 was developed for ethylene glycol alone. NIOSH investigators have recently determined that this method may have deficiencies when used to identify and quantitate other similar glycols as were encountered in this evaluation (such as propylene, butylene, diethylene, and triethylene glycols). In at least one instance ethylene glycol was incorrectly identified in an air sample. Since it is possible that interferences from other glycol analytes may have occurred, only qualitative glycol sampling data will be discussed in the final report. The sections of this revised interim report affected by these analytical problems have been highlighted. A thorough discussion of the analytical problems encountered while using NIOSH Sampling and Analytical Method 5500 for these glycols will be contained in the final report.
exposed actors (grouped by show) were compared to responses from control productions (Figure 1). Productions in which a statistically significant difference could be observed between the prevalence of symptoms among smoke exposed vs. control responses are marked with an asterisk (p <0.05).

**Grand Hotel**

Members of the cast in *GRAND HOTEL* were 2.73 times more likely to report problems during performances with wheezing (Relative Risk (RR)=2.73; 95% Confidence Interval (CI): 1.11-6.68), and breathlessness (RR=2.73; 95% CI:1.11-6.68) than were cast members in control productions. Five of the 33 cast members met the case definition for the lower respiratory tract symptoms (See Evaluation Design and Methods--Medical Evaluation), 19 (58%) met the case definition for upper respiratory tract symptoms, and five (15%) met the definition for eye symptom group. These numbers, however, were not sufficiently high to show a statistically significant increase over controls. When we excluded smokers from the analysis, actors in this production had an increased prevalence of frequent sputum production compatible with bronchitis when compared to controls (RR=2.63; 95% CI:1.05-6.54).
Les Miserables

*LES MISERABLES* cast members were more likely than controls to report headaches (RR=2.57; 95% CI:1.52-4.34), nausea (RR=3.21; 95% CI:1.38-7.47), runny nose (RR=2.46; 95% CI:1.62-3.74), stuffy nose (RR=2.67; 95% CI:1.84-3.87), sneezing (RR=2.70; 95% CI:1.68-4.33), coughing (RR=3.29; 95% CI:2.04-5.30), wheezing (RR=3.54; 95% CI:1.55-8.05), shortness of breath (RR=4.18; 95% CI:1.90-9.20) chest tightness (RR=5.66; 95% CI:2.12-15.11), dry eyes (RR=4.00; 95% CI:2.56-6.24), sore/itchy/watery eyes, (RR=3.60; 95% CI:1.77-7.33), burning eyes (RR=3.97; 95% CI:2.07-7.61), sore throat (RR=2.57; 95% CI:1.71-3.87), hoarseness (RR=1.73; 95% CI:1.37-2.19), and dry throat (RR=2.40; 95% CI:1.72-3.36).

Twelve of the 35 actors from *LES MISERABLES* met the case definition for the lower respiratory tract symptoms compared to controls: (RR=5.14; 95% CI:2.09-12.64), 31 met the definition for upper respiratory tract symptoms (RR=2.21; 95% CI:1.67-2.93), and 17 met the definition for eye symptoms (RR=4.86; 95% CI:2.39-9.85). Actors in this production also had a prevalence of frequent sputum production almost five-times that of controls (RR=4.88; 95% CI:2.32-10.24).

Phantom of the Opera

*PHANTOM OF THE OPERA* actors were more likely than controls to report runny nose (RR=2.00; 95% CI:1.24-3.23), stuffy nose (RR=2.31; 95% CI:1.53-3.48), sneezing (RR=2.10; 95% CI:1.22-3.62), coughing (RR 2.17; 95% CI:1.21-3.88), shortness of breath (RR=3.00; 95% CI:1.23-7.30), dry eyes (RR=2.50; 95% CI:1.45-4.32), sore/itchy/watery eyes (RR=4.20; 95% CI:2.09-8.44), burning eyes (RR=2.45; 95% CI:1.13-5.34), and hoarseness (RR=2.00; 95% CI:1.17-3.42).

Seven of the 30 actors from *PHANTOM OF THE OPERA* met the case definition for lower respiratory tract symptoms compared to controls: (RR=3.5; 95% CI:1.28-9.60), 20 met the definition for upper respiratory tract symptom (RR=1.67; 95% CI:1.17-2.38), and 14 met the definition for eye symptoms (RR=4.72; 95% CI:2.25-9.67).

Miss Saigon

*MISS SAIGON* cast members were more likely than controls to report headaches (RR=2.50; 95% CI:1.48-4.23), stuffy nose (RR=2.40; 95% CI:1.63-3.55), sneezing (RR=2.00; 95% CI:1.18-3.40), coughing (RR=2.50; 95% CI:1.48-4.23), shortness of breath (RR=4.06; 95% CI:1.84-8.96), chest tightness (RR=5.50; 95% CI:2.06-14.71), dry eyes (RR=3.06; 95% CI:1.87-4.98), sore/itchy/watery eyes (RR=3.75; 95% CI:1.86-7.56), burning eyes (RR=2.73; 95% CI:1.33-5.61), sore throat (RR=2.60 95% CI:1.74-
3.91), hoarseness (RR=2.74 95% CI:1.75-4.28) dry throat (RR=2.33; 95% CI:1.66-3.28).

Eight of the 36 actors from MISS SAIGON met the case definition for lower respiratory tract symptoms compared to controls: (RR=3.33; 95% CI:1.24-8.93), 29 met the definition for upper respiratory tract symptoms (RR=1.67; 95% CI:1.17-2.38), and 17 met the definition for eye symptoms (RR=4.72; 95% CI:2.32-9.60).

**DISCUSSION**

Based on the results of this evaluation, actors performing in the Broadway productions which used either a glycol-based or mineral oil-based theatrical smoke were more likely to report work-related mucous membrane irritation, upper respiratory symptoms, and lower respiratory symptoms. With the exception of theatrical smoke, no significant differences in the production environment were identified by the NIOSH investigators.

According to information provided by the manufacturers of the glycol-based smoke systems encountered during this evaluation, the three glycol solutions were normally heated to different temperatures in their respective smoke generating machines (290°C, 315°C, and 370°C). Aldehydes were detected in the headspace analysis of the one bulk sample which was heated to 370°C (≈700°F). Although the analysis is only qualitative, the presence of these aldehydes as decomposition products in the bulk sample heated to 370°C (and not in the glycol bulk samples heated to lower temperatures) may be significant in assessing the irritant potential of theatrical smoke. As a group, the aldehydes are well known skin, eye, and upper respiratory irritants.

Although theatrical smoke was visibly evident during all of the dress rehearsals and live performances, PBZ and GA air samples collected on actors, stage managers, and stage crew had very low concentrations of smoke constituents when compared to applicable OSHA, ACGIH, or NIOSH exposure limits. For example, acrolein and acetaldehyde, suspected by investigators to be possible decomposition products from the heating of the glycol-based fog fluids, were not found on any of the PBZ or GA air samples collected during this survey. Results from all of the PBZ air samples collected for formaldehyde were not detectable. The results from three GA air samples collected for formaldehyde during a performance of MISS SAIGON ranged from 0.02 to 0.05 ppm. These formaldehyde levels, which were similar to ambient formaldehyde concentrations measured outside several of the theaters where the "smoke productions" were held, are too low to cause irritation in most people.
As shown in Table 3, only 21 out of the 120 PBZ and GA air samples collected for glycols (ethylene, propylene, 1-3 butylene, diethylene, and triethylene) during this investigation had detectable amounts of these substances. Excluding the results from two GA air samples for glycols collected adjacent to smoke machines used during the LES MISERABLES dress rehearsal, all of the remaining glycol concentrations were very low, ranging from not detectable to 2.1 mg/m³.

Two of the GA air samples collected during LES MISERABLES were obtained at floor level directly next to the smoke machines (stage right and stage left). Levels of ethylene glycol in these samples ranged up to 21 mg/m³, TWA over the sampling period (approximately three hours). While these results were the highest measured during all of the productions, the samplers were positioned near each smoke machine outlet and, thus, were not representative of an actor's personal exposure. Nevertheless, all of the glycol concentrations were well below the short-term (15 minutes) OSHA PEL and ACGIH TLV of 127 mg/m³ for ethylene glycol. There are no OSHA, NIOSH, or ACGIH exposure criteria for the other glycols.

**CONCLUSIONS**

The evaluation request was submitted because of the performers' concern about the acute and possible chronic effects of exposure to theatrical smoke. The results from the questionnaire show that the actors in productions that utilize theatrical smoke report significantly more mucous membrane irritative symptoms than do the performers in the "non-smoke" productions. The results also show a higher prevalence of cough, shortness of breath, wheezing, and chest tightness among the actors in the "smoke productions."

Although some of the constituents of theatrical smoke (primarily the glycols) have irritative and mucous membrane drying properties, the reason for the high symptom prevalence in the productions that use theatrical smoke is not clear, since the TWA concentrations of the glycols measured during the performances are quite low. It is possible however, that the smoke concentrations could be sufficiently high during the short periods of time that the smoke is generated to contribute to the symptoms reported by the actors. One NIOSH investigator experienced throat irritation when encountering the theatrical smoke while performing the survey.
The air sampling data suggest that short-term "peak" exposures to glycol or mineral oil aerosols occur throughout a performance, coinciding with the periods during which the smoke is used during that play. If these peak exposures are sufficiently high to produce the work-related irritation reported by some of the actors, it would be reasonable to modify the factors which may influence an actor's exposure to the smoke. For example, relocating the smoke machine(s) to avoid exposing actors to the direct, concentrated release of the glycol (or mineral oil) aerosols may be advantageous in reducing complaints. Additionally, reducing the amount of theatrical smoke to the minimum necessary would also be advisable.

**RECOMMENDATIONS**

The air sampling data collected during this survey suggest that short-term "peak" exposures to theatrical smoke probably occur throughout any performance, coinciding with the smoke cues for that particular production. These peak exposures may be sufficiently high to help cause the work-related irritation reported by some of the actors. Smoke machines should be located to minimize actors' exposure to the concentrated aerosol as it first exits the machine. The quantity and frequency of use of the various fogs during a performance should be minimized.

**FUTURE ACTIONS**

1. While some mucous membrane irritative symptoms (eyes, nose, throat) might be expected, the high prevalence of work-related lower respiratory symptoms (cough, wheeze, chest tightness, and shortness of breath) reported by the smoke-exposed actors was surprising. It is possible that the questionnaire was too sensitive in its design and caused an over-reporting of symptoms by the respondents or the constituents of theatrical smoke may be more irritative at low concentrations than previously documented. It is also possible that there may be other factors involved. Since the etiology of the respiratory symptoms is unclear at this time, a return visit is planned to gather further information regarding the nature of these symptoms.

2. Development of a new NIOSH Sampling and Analytical Method for propylene, ethylene, diethylene, triethylene, tetraethylene, and 1,3 butylene glycols has been requested from the NIOSH Division of Physical Sciences and Engineering. Although not planned at this time, additional PBZ and/or GA air samples for these glycols may be collected as part of a follow-up evaluation.

Comments:

1. Heating temperatures are approximate and are based on information obtained from the manufacturers.
2. The aldehydes included in the sampling protocol were suspected of being likely decomposition by-products after heating the glycol solutions.

</tr>
<tr>
<td>1,3 Butylene Glycol</td>
<td>Liquid is thick and nearly colorless.</td>
<td>Used in food additives and flavorings. The substance is also used in production of polyesters, polyurethanes, and as a solvent.</td>
<td>The 1,3 isomer of butylene glycol is especially low in toxicity and is used in certain cosmetic and pharmaceutical applications. Has not been demonstrated to have carcinogenic, mutagenic, or teratogenic effects in animal studies. Not irritating to the skin. In studies involving human exposures, 1-3 butylene glycol has been shown to be capable of causing severe stinging of the eyes.</td>
<td>OSHA PEL: NONE ACGIH TLV: NONE NIOSH REL: NONE</td>
</tr>
<tr>
<td>Triethylene Glycol</td>
<td>Liquid is colorless and practically odorless.</td>
<td>Used as a solvent in vinyl, polyester, and resins; in printing inks; and for dehydrating natural gas.</td>
<td>Acute and chronic oral toxicity is very low. Has not been shown to be a significant skin or eye irritant. Unlikely that significant quantities of this compound could be absorbed through the skin.</td>
<td>OSHA PEL: NONE ACGIH TLV: NONE NIOSH REL: NONE</td>
</tr>
<tr>
<td>Diethylene Glycol</td>
<td>Liquid is syrupy, colorless and nearly odorless. Sweet taste.</td>
<td>Used as a textile softener; solvent for dyes, oils, adhesives; cosmetics, and in antifreeze solutions.</td>
<td>Minor to insignificant skin or eye irritant. Although animal data suggest little hazard from short-term inhalation, exposures to vapor, fog or mist should be minimized, especially in chronic (i.e. long-term) exposure situations. Animal studies (mice) indicate that this substance is a reproductive toxicant affecting fertility and reproductive performance (when given at high doses).</td>
<td>OSHA PEL: NONE ACGIH TLV: NONE NIOSH REL: NONE</td>
</tr>
</tbody>
</table>

Comments:
1. Laboratory identification of some of the higher molecular weight glycols (tetraethylene, pentaethylene, hexaethylene, etc.) in one of the bulk samples was not possible. These compounds are not discussed in this table.

2. Except as otherwise noted, the information presented in this table was obtained from the following sources: Patty's *Industrial Hygiene and Toxicology*; Proctor, Hughes and Fischman *Chemical Hazards of the Work Place*; and the American Conference of Governmental Industrial Hygienists' *Documentation of the Threshold Limit Values and Biological Exposure Indices*.

**Comments and Footnotes:**

All air concentrations are expressed in milligrams of material per cubic meter of air (mg/m³). All of the concentrations shown above were calculated as the time-weighted average over the period sampled. The sampling period was the duration of the play.

a There is no NIOSH REL for ethylene glycol. However, because of the potential teratogenicity and the known respiratory irritation at the level adopted for the OSHA PEL, NIOSH suggests that OSHA reconsider their current PEL for ethylene glycol.

Comments and Abbreviations:

a. General area air samples for formaldehyde collected following NIOSH Sampling and Analytical Method 3500 (impingers filled with 1% sodium bisulfite solution). This method offers the best sensitivity for formaldehyde.
b. Orchestra level located above the stage in *GRAND HOTEL*. In all the other productions the orchestra was located in front of and below the stage level.
c. NIOSH considers formaldehyde a suspect human carcinogen and recommends that exposures be kept as low as feasible.

TWA = time weighted average
STEL = short-term exposure limit (15 minutes)

EVALUATION CRITERIA: OIL MIST

OSHA Permissible Exposure Limit: 5 mg/m³

NIOSH Recommended Exposure Limit: m³ (10 hour time-weighted average exposure limit)
10 mg/m³ (15 minute short-term exposure limit)

ACGIH Threshold Limit Value: 5 mg/m³

COMMENTS AND ABBREVIATIONS:

a All oil mist concentrations are time-weighted averages over the time period sampled and are expressed in milligrams of oil mist per cubic meter of air.

b These concentrations fell between the limit of detection and limit of quantitation for this sample set. This means that oil mist was detectable but could not be reliably measured because of the small amount present.

Please fill in or check the appropriate box.

1. Age [ ] 14 [ ] 15 [ ] 16 [ ] 17 [ ] 18 [ ] 19 [ ] 20 [ ] 21 [ ] 22 [ ] 23 [ ] 24 [ ] 25 [ ] 26 [ ] 27 [ ] 28 [ ] 29 [ ] 30 [ ] 31 [ ] 32 [ ] 33 [ ] 34 [ ] 35 [ ] 36 [ ] 37 [ ] 38 [ ] 39 [ ] 40 [ ] 41 [ ] 42 [ ] 43 [ ] 44 [ ] 45 [ ] 46 [ ] 47 [ ] 48 [ ] 49 [ ] 50 [ ] 51 [ ] 52 [ ] 53 [ ] 54 [ ] 55 [ ] 56 [ ] 57 [ ] 58 [ ] 59 [ ] 60 [ ] 61 [ ] 62 [ ] 63 [ ] 64 [ ] 65 [ ] 66 [ ] 67 [ ] 68 [ ] 69 [ ] 70 [ ] 71 [ ] 72 [ ] 73 [ ] 74 [ ] 75 [ ] 76 [ ] 77 [ ] 78 [ ] 79 [ ] 80 [ ] 81 [ ] 82 [ ] 83 [ ] 84 [ ] 85 [ ] 86 [ ] 87 [ ] 88 [ ] 89 [ ] 90 [ ] 91 [ ] 92 [ ] 93 [ ] 94 [ ] 95 [ ] 96 [ ] 97 [ ] 98 [ ] 99 [ ] 100 [ ]

2. Gender [ ] Male [ ] Female

3. How long have you appeared in this production? [ ] 3 months

4. How long have you been a professional actor? [ ] 3 years [ ] 3 months

5. Please approximate the percent of time you are on stage during your performance:
   [ ] 30 min. or less [ ] 30 min. to 1 hr. [ ] 1 to 1.5 hrs [ ] 1.5 to 2 hrs [ ] 2 hrs +

6. Do you smoke cigarettes? [ ] Yes [ ] No
   [ ] (do not count smoking in a performance)

   if yes: [ ] 6a. How many cigarettes per day do you smoke?
   [ ] Cigarettes per day [ ]

   [ ] 6b. What is the total number of years you have smoked?
   [ ] Years smoked

7. Does the role you play require you to smoke during a performance? [ ] Yes [ ] No

8. Have you had a cold in the last week? [ ] Yes [ ] No

9. Have you been affected by allergies in the last week? [ ] Yes [ ] No

10. Do you have any of the following respiratory conditions?
    [ ] Chronic Bronchitis
    [ ] Asthma
    [ ] Recurrent Infections

11. Do you usually cough up phlegm from your chest? [ ] Yes [ ] No

11a. If yes: Do you usually cough up phlegm like this as much as twice a day, four or more days out of the week? [ ] Yes [ ] No

12. Are you currently taking any medications? [ ] Yes [ ] No

12a. If yes please specify: _____________________________

Please continue on the other side...
Answer the first question for each symptom. If the response is 'never', then go down the list to the next symptom.

COUGH

1. Do you usually cough first thing in the morning?
   1. Yes  G  2. No  G  

   Count a cough with the first cigarette or on first going out of doors.
   Exclude clearing the throat or a single cough.
   "Usually" means 4 or more days per week.

2. Do you usually cough during the day?
   1. Yes  G  2. No  G  

   Ignore an occasional cough.
   "Usually" means 4 or more days per week.

   (If "NO" to BOTH questions #1 and #2, go to the "PHLEGM" section below.)
   (If "YES" to either #1 or #2 answer questions in the box below and continue.)

<table>

PHLEGM

3. Do you usually bring up any phlegm from your chest on getting up, or first thing in the morning?
   1. Yes  G  2. No  G  

   Count phlegm with first cigarette or on first going out of doors.
   Exclude phlegm from the nose.
   Count swallowed phlegm.
   "Usually" means 4 or more days per week.

4. Do you usually bring up phlegm from your chest during the day?
   1. Yes  G  2. No  G  

   "Usually" means 4 or more days per week.
   Answer "YES" if it occurs twice or more.

   (If "NO" to BOTH questions #3 and #4, go to question #5.)
   (If "YES" to either #3 or #4, answer questions in the box below and continue.)
4a. Do you bring up phlegm like this on most days for as much as three months during the year?
   1. Yes G  2. No G

4b. If yes, how many years have you brought up phlegm like this? ________# years

**RESPIRATORY**

5. Are you troubled by shortness of breath when hurrying on level ground or walking up a slight hill?
   1. Yes G  2. No G

   *(If "YES" to #5, answer questions in the box below. If "NO," go to question #6.)*

<table>
<thead>
<tr>
<th>5a.</th>
